1 Introduction

This article introduces usage of the LMGene package. LMGene has been developed mainly for analysis of microarray data using a linear model and glog data transformation in the R statistical package.

2 Data preparation

LMGene takes objects of class ExpressionSet, which is the standard data structure of the Biobase package. Hence, if data which is of class ExpressionSet already, the user can jump to further steps, like diagnostic plotting or g-log transformation. Otherwise, the user needs to generate new objects of class ExpressionSet. For more detail, please see the vignette, 'Textual Description of Biobase' in the Biobase package.

Note: ExpressionSet. In this package, an object of class ExpressionSet must produce proper data using the commands exprs(object) and phenoData(object).

Example. LMGene includes a sample array data which is of class ExpressionSet. Let's take a look this sample data.

- 1. First, load the necessary packages in your R session.
 - > library(LMGene)
 - > library(Biobase)
 - > library(tools)
- 2. Load the sample ExpressionSet class data in the package LMGene.

```
> data(sample.eS)
```

3. View the data structure of the sample data and the details of exprs and phenoData slots in the data.

```
> slotNames(sample.eS)

Data generation. If you don't have ExpressionSet class data, you need to make some. LMGene provides a function that can generate an object of class ExpressionSet, assuming that there are array data of matrix class and experimental data of list class.

1. The package has sample array and experimental data, sample.mat and vlist.

```
> data(sample.mat)
                     > dim(sample.mat)
                       [1] 613 32
                      > data(vlist)
                      > vlist

2. Generate ExpressionSet class data using neweS function.
                      > test.eS <- neweS(sample.mat, vlist)
                     > class(test.eS)
                       [1] "ExpressionSet"
                     attr(,"package")
                       [1] "Biobase"
                     > identical(sample.eS, test.eS)
```

c.f. If you have different types of array data, such as RGList, marrayRaw, and so on, you can convert them into ExpressionSet class by using as method after installing convert package.

3 G-log transformation

[1] FALSE

1. Estimating parameters for g-log transformation. The linear model is not applied to the raw data, but to transformed and normalized data. Many people use a log transform. LMGene uses a log-like transform involving two parameters. We estimate the parameters λ and α of the generalized log transform $\log(y - \alpha + \sqrt{(y - \alpha)^2 + \lambda}) = \sinh^{-1}(\frac{y - \alpha}{\lambda}) + \log(\lambda)$ using the function tranest as follows:

```
> tranpar <- tranest(sample.eS)
> tranpar

$lambda
[1] 726.6187

$alpha
[1] 56.02754
```

The optional parameter ngenes controls how many genes are used in the estimation. The default is all of them (up to 100,000), but this option allows the use of less. A typical call using this parameter would be

```
> tranpar <- tranest(sample.eS, 100)</pre>
```

> tranpar

\$lambda

[1] 922.1549

\$alpha

[1] 58.29455

In this case, 100 genes are chosen at random and used to estimate the transformation parameter. The routine returns a list containing values for lambda and alpha.

- 2. G-log transformation. Using the obtained two parameters, the g-log transformed expression set can be calculated as follows.
 - > trsample.eS <- transeS(sample.eS, tranpar\$lambda, tranpar\$alpha)
 - > exprs(sample.eS)[1:3, 1:8]

3. Tranest options: multiple alpha, lowessnorm, model

Rather than using a single alpha for all samples, we can estimate a separate alpha for each sample. This allows for differences in chips, in sample concentration, or exposure conditions.

```
> tranparmult <- tranest(sample.eS, mult = TRUE)
```

> tranparmult

\$lambda

[1] 689.2819

\$alpha

- [1] 69.67146 37.02711 54.13904 69.35728 60.33270 60.75301 71.72965

- [29] 73.60255 89.48728 57.13887 64.98866

For vector alphas, transeS uses exactly the same syntax:

```
> trsample.eS <- transeS(sample.eS, tranparmult$lambda, tranparmult$alpha)
> exprs(trsample.eS)[1:3, 1:8]
```

```
p1d0 p1d1 p1d2 p1d3 p2d0 p2d1 p2d2 p2d3 g1 5.686954 5.424873 5.449682 4.549380 5.590642 5.418542 5.268332 5.347915 g2 6.272797 6.308464 5.592073 4.915159 6.811348 6.710929 5.693269 6.492140 g3 6.488757 6.493737 6.388361 5.832776 7.173087 6.830052 6.345199 7.029530
```

It's also possible to estimate the parameters using the more accurate lowess normalization (as opposed to uniform normalization):

```
> tranparmult <- tranest(sample.eS, ngenes = 100, mult = TRUE,
```

- + lowessnorm = TRUE)
- > tranparmult

\$lambda

[1] 594.2844

\$alpha

```
[1] 89.95468 54.91888 66.65733 65.61450 65.22170 73.01174 79.94544
```

- [8] 68.72582 54.39294 79.09616 67.01799 73.02480 71.79253 68.46500
- [15] 73.00550 105.69680 65.66677 59.77407 65.65676 73.48484 48.86901
- [22] 87.28417 55.35593 72.71866 182.48715 122.05815 56.92225 64.79629
- [29] 62.58358 79.97676 58.39496 65.90396

It is even possible now to estimate parameters using a specified model. For example, if we think that the interaction of variables in vlist is important, we can add interaction to the model:

```
> tranpar <- tranest(sample.eS, model = "patient + dose + patient:dose")
> tranpar
```

\$lambda

[1] 860.0836

\$alpha

[1] 55.68625

The model is always specified in the same way as the right-hand side of an lm model. In the example above, we set the parameters to minimize the mean squared error for a regression of transformed gene expression against patient, log dose, and their interaction.

Be very careful of using interactions between factor variables. If you do not have enough replications, you can easily overfit the data and have no errors to work with.

Naturally, it's possible to use mult, lowessnorm, and model all together.

4 Finding differentially expressed genes

- 1. Transformation and Normalization. Before finding differentially expressed genes, the array data needs to be transformed and normalized.
 - > trsample.eS <- transeS(sample.eS, tranparmult\$lambda, tranparmult\$alpha)
 > ntrsample.eS <- lnormeS(trsample.eS)</pre>
- 2. Finding differentially expressed genes The lmgene routine computes significant probes using the method of Rocke (2003). A typical call would be
 - > sigprobes <- LMGene(ntrsample.eS)</pre>

There is an optional argument, level, which is the test level, .05 by default. A call using this optional parameter would look like

```
> sigprobes <- LMGene(ntrsample.eS, level = 0.01)</pre>
```

The result is a list whose components have the names of the effects in the model. The values are the significant genes for the test of that effect or else the message "No significant genes".

As with tranest, it's possible to specify a more complex model to LMGene:

```
> sigprobes <- LMGene(ntrsample.eS, model = "patient+dose+patient:dose")
> sigprobes
```

\$patient
